Summary

Bayesian Variable Selection

$$y_i = \frac{\gamma_1 \beta_1 x_{i1} + \dots + \frac{\gamma_p \beta_p x_{ip}}{\gamma_p \beta_p x_{ip}} + \epsilon_i}{\epsilon_i \sim \mathsf{N}(0, \psi^{-1})}$$
$$i = 1, \dots, n$$

$$\boldsymbol{\beta} \sim \mathsf{N}(\mathbf{0}, \psi \boldsymbol{\Lambda} \mathbf{X}^{\top} \mathbf{X} \boldsymbol{\Lambda}), \text{ where } \boldsymbol{\Lambda} = \mathsf{diag}[\lambda_1, \dots, \lambda_p]$$

(1)

$$\gamma_j \sim \mathsf{Bern}(p_j), \ j=1,\ldots,p$$

$$\psi, \lambda_1^{-2},\ldots,\lambda_p^{-2} \sim \Gamma(c,d)$$

- Use MCMC methods to sample from posterior using software such as JAGS. Interested in two things:
 - ▶ Posterior model probabilities $P[\gamma = \gamma'|\mathbf{y}]$ for model γ' .
 - ▶ Posterior inclusion probabilities $P[\gamma_i = 1 | \mathbf{y}]$ for variable X_i .

Why Bayesian Variable Selection?

Some criticisms

- The end-game of model selection is often prediction. If so, better methods exist e.g. Lasso
- Why not just put a reasonable prior?
- Unreliable Gibbs sampler likely to get stuck in multiple modes.

Why Bayesian Variable Selection?

Some criticisms

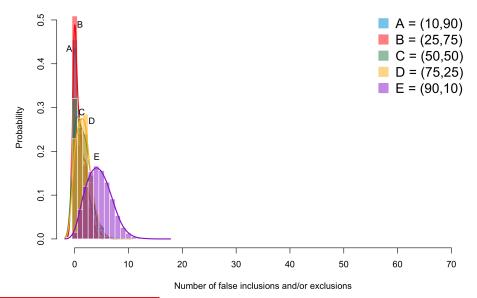

- The end-game of model selection is often prediction. If so, better methods exist e.g. Lasso
- Why not just put a reasonable prior?
- Unreliable Gibbs sampler likely to get stuck in multiple modes.

But actually,

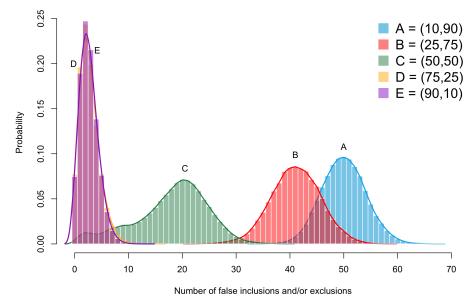

- Sometimes there is a need to know what is the most plausible, interpretable, and parsimonious model.
- Valid applications in social sciences, but perhaps not the p>n cases.
- Gibbs sampler not too terrible.
- For as many critics to this "combinatorial approach", there are equally as many proponents.
- Prediction through Bayesian model averaging.

Simulation results are good...

Bayesian Variable Selection

- 1 Modelling aerobic fitness through some exercise data (n = 30, p = 6) [SAS/STAT User Guide, 2008]
 - Agreed with forward selection and backward elimination procedure except in the Age variable.
 - ► Age negatively correlated with MaxPulse.
- 2 Effects of air pollution on mortality rate (n = 60, p = 15) [McDonald & Schwing, 1978]
 - ► Which of HC, NOx, and/or SO2 affects mortality rate in U.S. metropolitan areas?
 - ▶ Agreed with "ridge trace analysis" in identifying SO2.
- 3 Factors affecting ozone depletion (n = 178, p = 12,90) [Casella & Moreno, 2006]
 - ▶ Model obtained had smaller out-of-sample RMSE.
 - ► Selection of squared and two-way interaction terms to improve RMSE without overcomplicating the model.

- Bayesian Variable Selection

- 3 Bayesian I-prior linear models
- 4 Hamiltonian Monte Carlo
- **5** Summary

Introduction

• For i = 1, ..., n, consider the regression model

$$y_i = \alpha + f(\mathbf{x}_i) + \epsilon_i$$

 $(\epsilon_1, \dots, \epsilon_n) \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}^{-1})$

where $f \in \mathcal{F}$, $y_i \in \mathbb{R}$, and $\mathbf{x}_i = (x_{i1}, \dots, x_{ip}) \in \mathcal{X}$.

Introduction

• For i = 1, ..., n, consider the regression model

$$y_i = \alpha + f(\mathbf{x}_i) + \epsilon_i$$

 $(\epsilon_1, \dots, \epsilon_n) \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}^{-1})$

where $f \in \mathcal{F}$, $y_i \in \mathbb{R}$, and $\mathbf{x}_i = (x_{i1}, \dots, x_{in}) \in \mathcal{X}$.

 Definition (I-priors) For the regression model above, let \mathcal{F} be a reproducing kernel Hilbert space (RKHS) with kernel $h_{\lambda}: \mathcal{X} \times \mathcal{X} \to \mathbb{R}$. Then, assuming it exists, the Fisher information for I[f] for the function f is given by

$$I[f(\mathbf{x}_i), f(\mathbf{x}_i')] = \sum_{k=1}^n \sum_{l=1}^n \psi_{kl} h_{\lambda}(\mathbf{x}_i, \mathbf{x}_k) h_{\lambda}(\mathbf{x}_i', \mathbf{x}_l).$$

Let π be a Gaussian distribution on the random vector f with mean f_0 and covariance kernel I[f]. Then π is called an I-prior for f.

Function spaces and kernels

• There is a bijection between the set of all positive-definite functions (reproducing kernels) $h: \mathcal{X} \times \mathcal{X} \to \mathbb{R}$ and the set of all RKHS.

$\mathcal{X} = \{x_i\}$	Effect	Vector space ${\cal F}$	Kernel $h(x_i, x_k)$
Real	"Straight line" functions	Canonical	X_iX_k
Real	"Curvy" functions (smoothing)	Fractional Brownian Motion (FBM)	$ x_i ^{2\gamma} + x_k ^{2\gamma} - x_i - x_k ^{2\gamma}$ with $\gamma \in (0, 1)$
Nominal	Grouping	Pearson	$\frac{\mathbb{1}[x_i = x_k]}{p_i} - 1$ where $p_i = P[X = x_i]$

• The I-prior for f has the random-effect representation

$$f(\mathbf{x}_i) = \alpha + f_0(\mathbf{x}_i) + \sum_{k=1}^n h_{\lambda}(\mathbf{x}_i, \mathbf{x}_k) w_k$$

 $(w_1, \dots, w_n) \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}).$

Putting this back into our regression model, we obtain the w *I-prior* model

$$y_i = \alpha + f_0(\mathbf{x}_i) + \sum_{k=1}^n h_{\lambda}(\mathbf{x}_i, \mathbf{x}_k) w_k + \epsilon_i$$

 $(w_1, \dots, w_n) \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi})$
 $(\epsilon_1, \dots, \epsilon_n) \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}^{-1})$

• The I-prior for f has the random-effect representation

$$f(\mathbf{x}_i) = \alpha + f_0(\mathbf{x}_i) + \sum_{k=1}^n h_{\lambda}(\mathbf{x}_i, \mathbf{x}_k) w_k$$

 $(w_1, \dots, w_n) \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}).$

• Putting this back into our regression model, we obtain the w *I-prior* model

$$egin{aligned} \mathbf{y} &= lpha + \mathbf{f_0} + \mathbf{H_\lambda} \mathbf{w} + \epsilon \ & \mathbf{w} \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}) \ & \epsilon \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}^{-1}) \end{aligned}$$

• The I-prior for f has the random-effect representation

$$f(\mathbf{x}_i) = \alpha + f_0(\mathbf{x}_i) + \sum_{k=1}^n h_{\lambda}(\mathbf{x}_i, \mathbf{x}_k) w_k$$

 $(w_1, \dots, w_n) \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}).$

 Putting this back into our regression model, we obtain the w l-prior model

$$egin{aligned} \mathbf{y} &= lpha + \mathbf{f}_0 + \mathbf{H}_{m{\lambda}} \mathbf{w} + \epsilon \ & \mathbf{w} \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}) \ & \epsilon \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}^{-1}) \end{aligned}$$

• Typically, $(\mathbf{H}_{\lambda})_{ii} = \sum_{k=1}^{p} \lambda_k h_k(x_{ik}, x_{ik})$

• The I-prior for f has the random-effect representation

$$f(\mathbf{x}_i) = \alpha + f_0(\mathbf{x}_i) + \sum_{k=1}^n h_{\lambda}(\mathbf{x}_i, \mathbf{x}_k) w_k$$

 $(w_1, \dots, w_n) \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}).$

 Putting this back into our regression model, we obtain the w l-prior model

$$egin{aligned} \mathbf{y} &= lpha + \mathbf{f}_0 + \mathbf{H}_{m{\lambda}} \mathbf{w} + \epsilon \ & \mathbf{w} \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}) \ & \epsilon \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}^{-1}) \end{aligned}$$

• Typically, $\mathbf{H}_{\lambda} = \lambda_1 \mathbf{H}_1 + \cdots + \lambda_n \mathbf{H}_n$

• The I-prior for f has the random-effect representation

$$f(\mathbf{x}_i) = \alpha + f_0(\mathbf{x}_i) + \sum_{k=1}^n h_{\lambda}(\mathbf{x}_i, \mathbf{x}_k) w_k$$
$$(w_1, \dots, w_n) \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}).$$

Putting this back into our regression model, we obtain the w *I-prior* model

$$egin{aligned} \mathbf{y} &= lpha + \mathbf{f}_0 + \mathbf{H}_{m{\lambda}} \mathbf{w} + \epsilon \ & \mathbf{w} \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}) \ & \epsilon \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}^{-1}) \end{aligned}$$

• Typically, $\mathbf{H}_{\lambda} = \lambda_1 \mathbf{H}_1 + \cdots + \lambda_n \mathbf{H}_n$, $\mathbf{\Psi} = \psi \mathbf{I}_n$, and $\mathbf{f}_0 = \mathbf{0}$.

• The I-prior for f has the random-effect representation

$$f(\mathbf{x}_i) = \alpha + f_0(\mathbf{x}_i) + \sum_{k=1}^n h_{\lambda}(\mathbf{x}_i, \mathbf{x}_k) w_k$$

 $(w_1, \dots, w_n) \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}).$

• Putting this back into our regression model, we obtain the w *I-prior* model

$$egin{aligned} \mathbf{y} &= lpha + \mathbf{f}_0 + \mathbf{H}_{m{\lambda}} \mathbf{w} + \epsilon \ & \mathbf{w} \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}) \ & \epsilon \sim \mathsf{N}(\mathbf{0}, \mathbf{\Psi}^{-1}) \end{aligned}$$

- Typically, $\mathbf{H}_{\lambda} = \lambda_1 \mathbf{H}_1 + \cdots + \lambda_n \mathbf{H}_n$, $\mathbf{\Psi} = \psi \mathbf{I}_n$, and $\mathbf{f}_0 = \mathbf{0}$.
- Parameters of interest are $\theta = (\alpha, \lambda_1, \dots, \lambda_p, \psi)$.

Haziq Jamil (LSE) I-priors 3 Nov 2016 7 / 36

• The marginal distribution of **y** is normal with mean and variance

$$\begin{aligned} \mathsf{E}[\mathbf{y}] &= \alpha \\ \mathsf{Var}[\mathbf{y}] &= \psi \mathsf{H}_{\lambda}^2 + \psi^{-1} \mathsf{I}_n =: \mathsf{V}_{y} \end{aligned}$$

and thus, the marginal log-likelihood is given by

$$I(\boldsymbol{\theta}) = -\frac{n}{2}\log(2\pi) - \frac{1}{2}\log|\mathbf{V}_y| - \frac{1}{2}(\mathbf{y} - \boldsymbol{\alpha})^{\top}\mathbf{V}_y^{-1}(\mathbf{y} - \boldsymbol{\alpha}).$$

- MLE for intercept is $\hat{\alpha} = \bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i$.
- Usually no closed form estimates for λ and ψ , so use numerical optimisation to find MLE.
- Problem: Convergence is difficult when there are a lot of scale parameters.

EM algorithm

- A more stable method is using the EM algorithm. Treat the random effects w as "missing".
- The relevant distributions are easy enough to obtain:
 - $ightharpoonup \mathbf{y} \sim \mathsf{N}(\boldsymbol{\alpha}, \mathbf{V}_{\mathsf{v}})$
 - $\mathbf{w} \sim \mathsf{N}(\mathbf{0}, \psi \mathbf{I}_n)$
 - $\blacktriangleright \begin{pmatrix} \mathbf{y} \\ \mathbf{w} \end{pmatrix} \sim \mathsf{N} \left(\begin{pmatrix} \boldsymbol{\alpha} \\ \mathbf{0} \end{pmatrix}, \begin{pmatrix} \mathbf{V}_{y} & \psi \mathbf{H}_{\lambda} \\ \psi \mathbf{H}_{\lambda} & \psi \mathbf{I}_{n} \end{pmatrix} \right)$
 - $\mathbf{w}|\mathbf{y} \sim \mathsf{N}\left(\psi \mathbf{H}_{\lambda} \mathbf{V}_{\mathsf{v}}^{-1}(\mathbf{y} \alpha), \mathbf{V}_{\mathsf{v}}^{-1}\right)$
- For $t = 0, 1, \dots$ do:
 - ► E-step: Calculate $Q(\lambda, \psi) = \mathsf{E}_{\mathbf{w}} \left[\log f(\mathbf{y}, \mathbf{w}; \boldsymbol{\theta}) | \mathbf{y}; \lambda^{(t)}, \psi^{(t)}, \hat{\alpha} \right].$
 - ▶ M-step: $(\lambda^{(t+1)}, \psi^{(t+1)}) \leftarrow \arg \max_{(\lambda, \psi)} Q(\lambda, \psi)$.
- Problem: May be very slow to converge.

- An R package for regression modelling using I-priors.
 - Similar syntax to R's lm().
 - Parameters estimated using maximum likelihood.
 - Available on CRAN and GitHub.

Haziq Jamil (LSE) I-priors 3 Nov 2016 10 / 36

- An R package for regression modelling using I-priors.
 - Similar syntax to R's lm().
 - Parameters estimated using maximum likelihood.
 - Available on CRAN and GitHub.
- Example: Look at how students' mathematics achievement varies across different high schools (High School & Beyond dataset).

```
str(hsbsmall)
   'data.frame': 661 obs. of 3 variables:
##
    $ mathach : num 16.663 -2.155 0.085 18.804 2.409 ...
##
              : num 0.322 0.212 0.682 -0.148 -0.468 0.842 ...

- Other things available:
 - fitted() for fitted values.
 - predict() for fitted values of a new set of covariates.
 - ▶ resid() for model residuals.
 - logLik() and deviance() for model log-likelihood and deviance values respectively.
 - ▶ ipriorOptim() is a routine which combines EM algorithm and direct optimisation.

Haziq Jamil (LSE) I-priors 3 Nov 2016 10 / 36

- Bayesian Variable Selection
- 2 I-priors
- 3 Bayesian I-prior linear models
- 4 Hamiltonian Monte Carlo
- **5** Summary

The beta I-prior (linear) model

 For "straight line" functions in the Canonical RKHS, its kernel $h_{\lambda}: \mathcal{X} \times \mathcal{X} \to \mathbb{R}$ is defined as

$$h_{\lambda}(\mathbf{x}_i,\mathbf{x}_j) = \sum_{k=1}^{p} \lambda_k x_{ik} x_{jk}$$

The beta I-prior (linear) model

• For "straight line" functions in the Canonical RKHS, its kernel $h_{\lambda}: \mathcal{X} \times \mathcal{X} \to \mathbb{R}$ is defined as

$$\mathbf{H}_{\lambda} = \lambda_1 \mathbf{X}_1 \mathbf{X}_1^{\top} + \dots + \lambda_p \mathbf{X}_p \mathbf{X}_p^{\top}$$

The beta I-prior (linear) model

 For "straight line" functions in the Canonical RKHS, its kernel $h_{\lambda}: \mathcal{X} \times \mathcal{X} \to \mathbb{R}$ is defined as

$$\begin{aligned} \mathbf{H}_{\lambda} &= \lambda_1 \mathbf{X}_1 \mathbf{X}_1^{\top} + \dots + \lambda_{\rho} \mathbf{X}_{\rho} \mathbf{X}_{\rho}^{\top} \\ &= \mathbf{X} \mathbf{\Lambda} \mathbf{X}^{\top}, \end{aligned}$$

where $\Lambda = \text{diag}[\lambda_1, \dots, \lambda_p]$.

Haziq Jamil (LSE) I-priors 3 Nov 2016 11 / 36

The beta I-prior (linear) model

 For "straight line" functions in the Canonical RKHS, its kernel $h_{\lambda}: \mathcal{X} \times \mathcal{X} \to \mathbb{R}$ is defined as

$$\begin{aligned} \mathbf{H}_{\lambda} &= \lambda_1 \mathbf{X}_1 \mathbf{X}_1^{\top} + \dots + \lambda_p \mathbf{X}_p \mathbf{X}_p^{\top} \\ &= \mathbf{X} \mathbf{\Lambda} \mathbf{X}^{\top}, \end{aligned}$$

where $\Lambda = \text{diag}[\lambda_1, \dots, \lambda_n]$.

Putting this into the w I-prior model we have

$$\mathbf{y} = \alpha + \mathbf{H}_{\lambda} \mathbf{w} + \epsilon$$
$$= \alpha + \mathbf{X} \underbrace{\mathbf{\Lambda} \mathbf{X}^{\top} \mathbf{w}}_{\beta} + \epsilon$$

which implies $E[\beta] = \mathbf{0}$ and $Var[\beta] = \psi \Lambda \mathbf{X}^{\top} \mathbf{X} \Lambda$.

Haziq Jamil (LSE) 3 Nov 2016 11 / 36

The beta I-prior (linear) model cont.

• The standard multiple regression model with an I-prior on β

$$y_{i} = \alpha + \beta_{1}x_{i1} + \dots + \beta_{p}x_{ip} + \epsilon_{i}$$

$$\beta \sim \mathsf{N}(\mathbf{0}, \psi \mathbf{\Lambda} \mathbf{X}^{\top} \mathbf{X} \mathbf{\Lambda}), \text{ where } \mathbf{\Lambda} = \mathsf{diag}[\lambda_{1}, \dots, \lambda_{p}]$$

$$\epsilon_{i} \sim \mathsf{N}(\mathbf{0}, \psi^{-1})$$

$$i = 1, \dots, n$$
(2)

is an equivalent representation of the w I-prior model under the Canonical kernel.

Estimate this model via ML methods as before, or fully Bayes, as we will see soon.

Haziq Jamil (LSE) 3 Nov 2016 12 / 36

Comparison to ridge regression and Lasso

$$extit{Ridge}: \hat{oldsymbol{eta}}^R = \mathop{\mathrm{arg\,min}}_{oldsymbol{eta}} \|\mathbf{y} - \mathbf{X}oldsymbol{eta}\|^2 + \lambda \sum_{j=1}^p eta_j^2$$

Lasso:
$$\hat{\boldsymbol{\beta}}^L = \underset{\boldsymbol{\beta}}{\operatorname{arg min}} \|\mathbf{y} - \mathbf{X}\boldsymbol{\beta}\|^2 + \lambda \sum_{j=1}^{p} |\beta_j|$$

Haziq Jamil (LSE) I-priors 3 Nov 2016 13 / 36

Comparison to ridge regression and Lasso

Ridge:
$$\beta_1, \dots, \beta_p \sim N(0, 1/\lambda)$$

Lasso: $\beta_1, \dots, \beta_p \sim Laplace(0, 1/\lambda)$

Haziq Jamil (LSE) I-priors 3 Nov 2016 13 / 36

Comparison to ridge regression and Lasso

$$extit{Ridge}: eta_1, \dots, eta_p \sim \mathsf{N}(0, 1/\lambda) \ extit{Lasso}: eta_1, \dots, eta_p \sim \mathsf{Laplace}(0, 1/\lambda) \ extit{}$$

These only (typically) use one common shrinkage parameter λ .

Haziq Jamil (LSE) I-priors 3 Nov 2016 13 / 36

Comparison to ridge regression and Lasso

Ridge:
$$\beta_1, \dots, \beta_p \sim \mathsf{N}(0, 1/\lambda)$$

Lasso: $\beta_1, \dots, \beta_p \sim \mathsf{Laplace}(0, 1/\lambda)$

These only (typically) use one common shrinkage parameter λ .

- Other Bayesian Variable Selection priors
 - ▶ After standardising data **X**, use weakly informative priors

$$\boldsymbol{\beta} \sim \mathsf{N}(\mathbf{0}, 10 \mathbf{I}_p).$$

► The objective g-prior are also popular

$$\boldsymbol{\beta} \sim \mathsf{N}(\mathbf{0}, g(\mathbf{X}^{\top}\mathbf{X})^{-1}).$$

Haziq Jamil (LSE) 3 Nov 2016 13 / 36

Comparison to ridge regression and Lasso

Ridge:
$$\beta_1, \dots, \beta_p \sim \mathsf{N}(0, 1/\lambda)$$

Lasso: $\beta_1, \dots, \beta_p \sim \mathsf{Laplace}(0, 1/\lambda)$

These only (typically) use one common shrinkage parameter λ .

- Other Bayesian Variable Selection priors
 - ▶ After standardising data **X**, use weakly informative priors

$$\boldsymbol{\beta} \sim \mathsf{N}(\mathbf{0}, 10 \mathbf{I}_p).$$

▶ The objective *g*-prior are also popular

$$\boldsymbol{\beta} \sim \mathsf{N}(\mathbf{0}, g(\mathbf{X}^{\top}\mathbf{X})^{-1}).$$

• I-priors have individual shrinkage coefficients on the β , and also makes them correlated a priori.

Full Bayes estimation

The fully Bayes beta I-prior model is the following hierarchical model

$$y_i = \alpha + \beta_1 x_{i1} + \dots + \beta_p x_{ip} + \epsilon_i$$
$$\epsilon_i \sim N(0, \psi^{-1})$$
$$i = 1, \dots, n$$

$$\begin{split} \frac{\text{Priors}}{\alpha \sim \mathsf{N}(\mathsf{0}, \mathsf{a}^2)} \\ \boldsymbol{\beta} \sim \mathsf{N}(\mathbf{0}, \boldsymbol{\psi} \boldsymbol{\Lambda} \mathbf{X}^\top \mathbf{X} \boldsymbol{\Lambda}), \text{ where } \boldsymbol{\Lambda} = \mathsf{diag}[\lambda_1, \dots, \lambda_p] \\ \boldsymbol{\psi}, \lambda_1^{-2}, \dots, \lambda_p^{-2} \sim \Gamma(c, d) \end{split}$$

The posterior distribution is

$$f(\alpha, \beta, \psi, \lambda | \mathbf{y}) \propto f(\mathbf{y} | \alpha, \beta, \psi, \lambda) f(\alpha, \beta, \psi, \lambda)$$

$$\propto f(\mathbf{y} | \alpha, \beta, \psi) f(\alpha) f(\beta | \psi, \lambda) f(\psi) f(\lambda_1) \cdots f(\lambda_p)$$

Haziq Jamil (LSE)

Estimation using JAGS

- Fit Bayesian models using JAGS (or WinBUGS or OpenBUGS).
- In R, many packages to run JAGS models: rjags, R2Jags, runjags.
- We will use runjags as it allows easy parallelisation of chains.
- Simulate a dataset:

```
n < -100
p <- 2
beta.true \leftarrow matrix(c(10, 0), ncol = 1)
X <- matrix(rnorm(n * p, ncol = p)</pre>
Y \leftarrow X \% *\% beta.true + rnorm(n, mean = 0, sd = 2)
```

```
mod <- "
  model {
    for (i in 1:n) {
      Y[i] ~ dnorm(mu[i], psi)
      mu[i] <- alpha + inprod(X[i,1:p], beta[1:p])</pre>
    alpha ~ dnorm(0, 0.0001)
    psi ~ dgamma(0.1, 0.0001)
    for (j in 1:p) {
      lambdasq[j] ~ dgamma(0.0001, 0.0001)
      for (k \text{ in 1:p}) \{ LambdaInv[j, k] \leftarrow equals(j,k) * pow(lambdasq[k], -0.5) \}
    BetaPrec <- LambdaInv[1:p, 1:p] %*% XTX.inv %*% LambdaInv[1:p, 1:p] / psi
    beta[1:p] ~ dmnorm(rep(0, p), BetaPrec)
    sigma <- pow(psi, -0.5)
    lambda[1:p] <- pow(lambdasq[1:p], 0.5)</pre>
  #data# Y, X, XTX.inv, n, p
  #inits# alpha, beta, psi, lambdasq
  #monitor# alpha, beta, sigma, lambda
```

Estimation using JAGS

Haziq Jamil (LSE)

I-priors

3 Nov 2016

Problems

- Trace plot of λ_k can be very erratic, and samples found to be severely autocorrelated.
- Since the scale parameters are very important for Bayesian Variable Selection, it is imperative that these are estimated correctly.
- Suggestions:
 - ► Improve samples Hamiltonian Monte Carlo?
 - ▶ Treat λ as fixed, replacing them with estimates obtained using ML methods.

Haziq Jamil (LSE) I-priors 3 Nov 2016 17 / 36

- Bayesian Variable Selection
- 2 I-priors
- 3 Bayesian I-prior linear models
- 4 Hamiltonian Monte Carlo
- **5** Summary

Introduction

- Introduced as Hybrid Monte Carlo by Duane et. al. 1987 for use in lattice models of quantum theory.
- Statistical applications started appearing in the 1990s: Neal (1993, 1996), Isharawan (1999), Liu (2001).
- Development of HMC software (Stan) began in 2011, motivated by the difficulties faced when doing full Bayesian inference on multilevel generalised linear models (Gelman and Hill, 2007).
- The basic idea behind HMC is to use Hamiltonian dynamics to propose new states, instead of "random walks".

- High probability of acceptance
- Distant move

Hamiltonian dynamics

 A reformulation of classical mechanics which describes motion through Hamilton's equations:

$$\frac{\mathrm{d}\mathbf{x}}{\mathrm{d}t} = \frac{\partial H}{\partial \mathbf{p}} \text{ and } \frac{\mathrm{d}\mathbf{p}}{\mathrm{d}t} = -\frac{\partial H}{\partial \mathbf{x}},$$

where $H = H(\mathbf{x}, \mathbf{p})$ is the Hamiltonian of the system (total energy), and (x, p) are the position and momentum coordinates of the body in motion.

Hamiltonian dynamics

 A reformulation of classical mechanics which describes motion. through Hamilton's equations:

$$\frac{\mathrm{d}\mathbf{x}}{\mathrm{d}t} = \frac{\partial H}{\partial \mathbf{p}} \text{ and } \frac{\mathrm{d}\mathbf{p}}{\mathrm{d}t} = -\frac{\partial H}{\partial \mathbf{x}},$$

where $H = H(\mathbf{x}, \mathbf{p})$ is the Hamiltonian of the system (total energy), and (x, p) are the position and momentum coordinates of the body in motion.

In a closed system,

$$H(\mathbf{x},\mathbf{p}) = K(\mathbf{p}) + U(\mathbf{x})$$

Kinetic energy Potential energy

Hamiltonian dynamics

 A reformulation of classical mechanics which describes motion through Hamilton's equations:

$$\frac{d\mathbf{x}}{dt} = \frac{\partial H}{\partial \mathbf{p}} = \frac{\partial}{\partial \mathbf{p}} K(\mathbf{p}) \text{ and } \frac{d\mathbf{p}}{dt} = -\frac{\partial H}{\partial \mathbf{x}} = -\frac{\partial}{\partial \mathbf{x}} U(\mathbf{x}),$$

where $H = H(\mathbf{x}, \mathbf{p})$ is the Hamiltonian of the system (total energy), and (\mathbf{x}, \mathbf{p}) are the position and momentum coordinates of the body in motion.

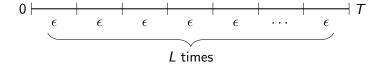

• In a closed system,

$$H(\mathbf{x}, \mathbf{p}) = K(\mathbf{p}) + U(\mathbf{x})$$

Kinetic energy Potential energy

Hamiltonian dynamics cont.

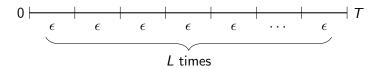

• To describe the evolution of $(\mathbf{x}(t), \mathbf{p}(t))$ from time t to t + T, it is necessary to discretise time and split $T = L \cdot \epsilon$.

Haziq Jamil (LSE) I-priors 3 Nov 2016 20 / 36

Hamiltonian dynamics cont.

• To describe the evolution of $(\mathbf{x}(t), \mathbf{p}(t))$ from time t to t + T, it is necessary to discretise time and split $T = L \cdot \epsilon$.

 Solve the system of differential equations using Euler's method, or the more commonly used leapfrog integration:

Step 1:
$$\mathbf{p}(t + \epsilon/2) = \mathbf{p}(t) - \frac{\epsilon}{2} \cdot \frac{\partial}{\partial \mathbf{x}} U(\mathbf{x}(t))$$

Step 2: $\mathbf{x}(t + \epsilon) = \mathbf{x}(t) + \epsilon \cdot \frac{\partial}{\partial \mathbf{p}} K(\mathbf{p}(t + \epsilon/2))$
Step 3: $\mathbf{p}(t + \epsilon) = \mathbf{p}(t + \epsilon/2) - \frac{\epsilon}{2} \cdot \frac{\partial}{\partial \mathbf{x}} U(\mathbf{x}(t + \epsilon))$

Steps 1-3 are repeated *L* times.

https://haziqjamil.shinyapps.io/hmc1/

• Given some energy function $E(\theta)$ over states θ , the canonical distribution of the states θ is given by the pdf

$$f(\theta) = \frac{1}{Z} \exp\left[-\frac{E(\theta)}{kT}\right].$$

where k is Boltzmann's constant, T is the absolute temperature of the system, and Z is a normalising constant.

• Given some energy function $E(\theta)$ over states θ , the canonical distribution of the states θ is given by the pdf

$$f(\theta) = \frac{1}{Z} \exp \left[-\frac{E(\theta)}{kT} \right].$$

where k is Boltzmann's constant, T is the absolute temperature of the system, and Z is a normalising constant.

• The Hamiltonian $H(\mathbf{x}, \mathbf{p}) = K(\mathbf{p}) + U(\mathbf{x})$ is one such energy function over states (\mathbf{x}, \mathbf{p}) .

Haziq Jamil (LSE) | I-priors | 3 Nov 2016 | 22 / 36

• Given some energy function $E(\theta)$ over states θ , the canonical distribution of the states θ is given by the pdf

$$f(\mathbf{x}, \mathbf{p}) = \frac{1}{Z} \exp \left[-\frac{H(\mathbf{x}, \mathbf{p})}{kT} \right].$$

where k is Boltzmann's constant, T is the absolute temperature of the system, and Z is a normalising constant.

• The Hamiltonian $H(\mathbf{x}, \mathbf{p}) = K(\mathbf{p}) + U(\mathbf{x})$ is one such energy function over states (\mathbf{x}, \mathbf{p}) .

Haziq Jamil (LSE) 3 Nov 2016 22 / 36

• Given some energy function $E(\theta)$ over states θ , the canonical distribution of the states θ is given by the pdf

$$f(\mathbf{x}, \mathbf{p}) = \frac{1}{Z} \exp \left[-\frac{H(\mathbf{x}, \mathbf{p})}{kT} \right].$$

where k is Boltzmann's constant, T is the absolute temperature of the system, and Z is a normalising constant.

- The Hamiltonian $H(\mathbf{x}, \mathbf{p}) = K(\mathbf{p}) + U(\mathbf{x})$ is one such energy function over states (x, p).
- Notice that the distribution for **x** and **p** are independent:

$$f(\mathbf{x}, \mathbf{p}) \propto \exp \left[-\frac{K(\mathbf{p})}{kT} \right] \exp \left[-\frac{U(\mathbf{x})}{kT} \right] = f(\mathbf{x})f(\mathbf{p}).$$

Haziq Jamil (LSE) 3 Nov 2016 22 / 36

• Given some energy function $E(\theta)$ over states θ , the canonical distribution of the states θ is given by the pdf

$$f(\mathbf{x}, \mathbf{p}) = \frac{1}{Z} \exp \left[-\frac{H(\mathbf{x}, \mathbf{p})}{kT} \right].$$

where k is Boltzmann's constant, T is the absolute temperature of the system, and Z is a normalising constant.

- The Hamiltonian $H(\mathbf{x}, \mathbf{p}) = K(\mathbf{p}) + U(\mathbf{x})$ is one such energy function over states (x, p).
- Notice that the distribution for **x** and **p** are independent:

$$f(\mathbf{x}, \mathbf{p}) \propto \exp \left[-\frac{K(\mathbf{p})}{kT} \right] \exp \left[-\frac{U(\mathbf{x})}{kT} \right] = f(\mathbf{x})f(\mathbf{p}).$$

• Typically, choose T such that kT = 1.

Choosing the energy functions

• Using a quadratic kinetic energy function $K(\mathbf{p}) = \mathbf{p}^{\top} \mathbf{M}^{-1} \mathbf{p}/2$ yields a normal density function

$$f(\mathbf{p}) \propto \exp\left[-rac{1}{2}\mathbf{p}^{ op}\mathbf{M}^{-1}\mathbf{p}
ight],$$

implying $\mathbf{p} \sim N_d(\mathbf{0}, \mathbf{M})$, where $\mathbf{M} = \text{diag}[m_1, \dots, m_d]$ is the mass matrix.

Haziq Jamil (LSE) 3 Nov 2016 23 / 36 • Using a quadratic kinetic energy function $K(\mathbf{p}) = \mathbf{p}^{\top} \mathbf{M}^{-1} \mathbf{p}/2$ yields a normal density function

$$f(\mathbf{p}) \propto \exp\left[-rac{1}{2}\mathbf{p}^{ op}\mathbf{M}^{-1}\mathbf{p}
ight],$$

implying $\mathbf{p} \sim N_d(\mathbf{0}, \mathbf{M})$, where $\mathbf{M} = \text{diag}[m_1, \dots, m_d]$ is the mass matrix.

As for the potential energy, choose a function such that

$$U(\mathbf{x}) = -\log f(\mathbf{x}),$$

since $f(\mathbf{x}) \propto \exp[-U(\mathbf{x})]$, where $f(\mathbf{x})$ is the target density from which we wish to sample.

Haziq Jamil (LSE) 3 Nov 2016 23 / 36

Stan

http://mc-stan.org

- Stan interfaces: R, Python, shell, MATLAB, Julia, Stata, and Mathematica. Runs on Linux. Mac and Windows.
- R package rstan uses Stan modelling language. For expression-based Bayesian regression modelling, package rstanarm is available.
- Nice things about Stan
 - Tuning is done automatically.
 - ▶ Vast library of differentiable probability functions, or code your own.
 - Conjugacy has no computational advantage.
 - ▶ Optimising for efficiency possible, e.g. vectorisation.

Haziq Jamil (LSE) I-priors 3 Nov 2016 26 / 36

HMC unable to sample from discrete distributions

- HMC requires that the domain of $f(\mathbf{x})$ is continuous and $\partial \log f(\mathbf{x})/\partial \mathbf{x}$ is inexpensive to compute.
- This is a problem for our Bayesian Variable Selection model because we need posterior samples of $\gamma \in \{0,1\}^p$.
- Three ideas:
 - ► Marginalise the discrete variables.
 - ▶ Use an underlying latent continuous variable.
 - ► Augment with Gibbs sampling.

Approach 1: Marginalise

- Let θ be some continuous parameters and γ be some discrete parameters in the model with data y.
- Since unable to sample from $f(\gamma|\mathbf{y})$, integrate out γ from the model, and just sample from the posterior of θ

$$f(\theta|\mathbf{y}) = \sum_{\gamma} f(\theta, \gamma|\mathbf{y}) = f(\theta) \sum_{\gamma} f(\mathbf{y}|\theta, \gamma) f(\gamma)$$

• The unnormalised posterior probability mass function for γ is

$$q(\gamma) = \frac{1}{M} \sum_{m=1}^{M} f(\boldsymbol{\theta}^{(m)}, \gamma | \mathbf{y})$$

where m = 1, ..., M is the index for the posterior draws.

 Problem: For Bayesian Variable Selection models, this is intractable because need to sum over all 2^p models.

Haziq Jamil (LSE) 3 Nov 2016 29 / 36

Approach 2: Latent continuous variables

• For the Bayesian Variable Selection model, assume there is underlying standard normal random variable Z_j for each $j=1,\ldots,p$ such that

$$\gamma_j = \begin{cases} 1 & Z_j \ge 0 \\ 0 & Z_j < 0 \end{cases}$$

- Probabilities are preserved: $P[\gamma_i = 1] = P[Z_i \ge 0] = 0.5$.
- Problems:
 - ▶ Does this make sense?
 - ▶ The discrete variables still "exist", so possibly derivatives will break.

Approach 3: Use Gibbs sampler

- Sample the continuous parameters θ using HMC.
- At each iteration m, use $\theta^{(m)}$ in the Gibbs conditional densities to sample γ .
- Problem: Have to write code for the HMC sampler, which won't include all the automatic tuning that Stan has.

- Bayesian Variable Selection
- 2 I-priors
- 3 Bayesian I-prior linear models
- 4 Hamiltonian Monte Carlo
- **6** Summary

Summary

- For our I-prior Bayesian Variable Selection model
 - Promising results in both simulated and real-world data.
 - ▶ The individual scale parameters $\lambda_1, \ldots, \lambda_p$ are important.
 - We have used ML estimate for λ in our Bayesian model.
- Things I want to do
 - ▶ Any model consistency results for Bayesian variable selection models?
 - Any mathematical justification as to why we should use individual scale parameters?
 - ► How does the off-diagonal elements in the I-prior covariance matrix help things?
- Wishlist: Make HMC work for Bayesian variable selection models.

What we've seen today

- 1 I-prior models estimated using ML methods (EM algorithm) and use of the iprior package in R.
- 2 Shrinkage properties of I-priors for use in Bayesian variable selection.
- 3 Bayesian estimation in JAGS.
- 4 Shiny apps for reactive programming.
- 5 Hamiltonian dynamics and Hamiltonian Monte Carlo.
- 6 Bayesian inference using HMC via Stan.
- 7 knitr for combining (evaluated) R code and plots into documents.
- 8 Git and GitHub for version control.

knitr example

You type:

```
<<chunk.name, echo = TRUE>>=
x \leftarrow rnorm(100)
max(x)
hist(x)
```

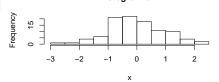

0

• The output:

```
x \leftarrow rnorm(100)
max(x)
## [1] 2.375356
```

hist(x)

Histogram of x

Additional material

- Very fast algorithm to obtain MLEs of mixed-effects models by using sparse Cholesky decomposition.
- Consider the mixed-effects model

$$\mathbf{y} = \mathbf{X}\boldsymbol{eta} + \mathbf{Z}\mathbf{b} + \boldsymbol{\epsilon} \ \epsilon \sim \mathsf{N}(\mathbf{0}, \sigma^2 \mathbf{I}_n) \ \mathbf{b} \sim \mathsf{N}(\mathbf{0}, \mathbf{\Sigma})$$

• Suppose that $\mathbf{\Sigma} = \sigma^2 \mathbf{\Lambda}_{\theta} \mathbf{\Lambda}_{\theta}^{\top}$. Then the following model is equivalent, where we have used the substitution $\mathbf{b} = \mathbf{\Lambda}_{\theta} \mathbf{u}$:

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\mathbf{\Lambda}_{\boldsymbol{\theta}}\mathbf{u} + \boldsymbol{\epsilon}$$

$$\boldsymbol{\epsilon} \sim \mathsf{N}(\mathbf{0}, \sigma^2\mathbf{I}_n)$$

$$\mathbf{u} \sim \mathsf{N}(\mathbf{0}, \sigma^2\mathbf{I}_n)$$

• The density of interest is $f(y) = \int h(u) du$, where

$$h(\mathbf{u}) = f(\mathbf{y}|\mathbf{u})f(\mathbf{u})$$

$$= (2\pi\sigma^2)^{-(n+q)/2} \exp\left[-\frac{\|\mathbf{y} - \mathbf{X}\boldsymbol{\beta} - \mathbf{Z}\boldsymbol{\Lambda}_{\boldsymbol{\theta}}\mathbf{u}\|^2 + \|\mathbf{u}\|^2}{2\sigma^2}\right]$$

 Haziq Jamil (LSE)
 I-priors
 3 Nov 2016

• The density of interest is $f(y) = \int h(u) du$, where

$$h(\mathbf{u}) = f(\mathbf{y}|\mathbf{u})f(\mathbf{u})$$

$$= (2\pi\sigma^2)^{-(n+q)/2} \exp\left[-\frac{\|\mathbf{y} - \mathbf{X}\boldsymbol{\beta} - \mathbf{Z}\boldsymbol{\Lambda}_{\boldsymbol{\theta}}\mathbf{u}\|^2 + \|\mathbf{u}\|^2}{2\sigma^2}\right]$$

• Each calculation of f(y) involves obtaining the conditional modes

$$\tilde{\mathbf{u}}(\boldsymbol{\theta}, \boldsymbol{\beta}) = \operatorname*{arg\,min}_{\mathbf{u}} d(\mathbf{u}, \boldsymbol{\theta}, \boldsymbol{\beta})$$

by computing the sparse Cholesky factorisation

$$\mathbf{L}_{m{ heta}}\mathbf{L}_{m{ heta}}^{ op}=\mathbf{\Lambda}_{m{ heta}}^{ op}\mathbf{Z}^{ op}\mathbf{Z}\mathbf{\Lambda}_{m{ heta}}+\mathbf{I}_{m{q}},$$

and solving $\mathbf{L}_{\boldsymbol{\theta}}^{\top}\tilde{\mathbf{u}} = c(\boldsymbol{\theta}, \boldsymbol{\beta})$ by back substitution.

Haziq Jamil (LSE) I-priors 3 Nov 2016 38 / 36

• For linear mixed models, $f(\mathbf{y}) = \int h(\mathbf{u}) d\mathbf{u}$ has a closed-form expression in terms of \mathbf{L}_{θ} and $\tilde{\mathbf{u}}(\theta, \boldsymbol{\beta})$:

$$f(\mathbf{y}) = (2\pi\sigma^2)^{-n/2} |\mathbf{L}_{\boldsymbol{\theta}}|^{-1} \exp\left[-\frac{d(\tilde{\mathbf{u}}, \boldsymbol{\theta}, \boldsymbol{\beta})}{2\sigma^2}\right]. \tag{4}$$

• On the deviance scale, we have $D(\theta, \beta, \sigma) = -2 \log f(\mathbf{y})$. The value of σ which minimises the deviance is

$$\sigma^2(\boldsymbol{\theta},\boldsymbol{\beta}) = \frac{d(\tilde{\mathbf{u}},\boldsymbol{\theta},\boldsymbol{\beta})}{n}.$$

Plugging this back into (4), we obtain the profiled deviance

$$D(\boldsymbol{\theta}, \boldsymbol{\beta}) = 2\log |\mathbf{L}_{\boldsymbol{\theta}}| + n\left(1 + \log\left(2\pi \frac{d(\tilde{\mathbf{u}}, \boldsymbol{\theta}, \boldsymbol{\beta})}{n}\right)\right)$$

which is then minimised to obtain MLEs $\hat{\theta}$, $\hat{\beta}$ and $\sigma^2(\hat{\theta}, \hat{\beta})$.

- "Eliminate" fixed effects β .
 - Find conditional modes $\tilde{\beta}(\theta)$

$$\begin{pmatrix} \tilde{\mathbf{u}}(\boldsymbol{\theta}) \\ \tilde{\boldsymbol{\beta}}(\boldsymbol{\theta}) \end{pmatrix} = \operatorname*{arg\,min}_{(\mathbf{u},\boldsymbol{\beta})} d(\mathbf{u},\boldsymbol{\beta},\boldsymbol{\theta})$$

via a sparse Cholesky decomposition. Following a similar method as before, obtain a profiled deviance which depends only on θ

$$D(\boldsymbol{\theta}) = 2 \log |\mathbf{L}_{\boldsymbol{\theta}}| + n \left(1 + \log \left(2\pi \frac{d(\tilde{\mathbf{u}}, \boldsymbol{\theta}, \tilde{\boldsymbol{\beta}})}{n} \right) \right).$$

- "Eliminate" fixed effects β.
 - Find conditional modes $\tilde{\beta}(\theta)$

$$egin{pmatrix} ilde{\mathbf{u}}(m{ heta}) \ ilde{eta}(m{ heta}) \end{pmatrix} = rg\min_{(\mathbf{u},m{eta})} d(\mathbf{u},m{eta},m{ heta})$$

via a sparse Cholesky decomposition. Following a similar method as before, obtain a profiled deviance which depends only on θ

$$D(\boldsymbol{\theta}) = 2 \log |\mathbf{L}_{\boldsymbol{\theta}}| + n \left(1 + \log \left(2\pi \frac{d(\tilde{\mathbf{u}}, \boldsymbol{\theta}, \tilde{\boldsymbol{\beta}})}{n} \right) \right).$$

▶ In addition, use the restricted maximum likelihood (REML) criterion

$$D_R(\boldsymbol{\theta}, \sigma) = -2 \log \int f(\mathbf{y}) \, \mathrm{d}\boldsymbol{\beta}.$$

Again, follow similar steps to obtain the profiled REML criterion

$$D_R(\boldsymbol{\theta}) = 2\log(|\mathbf{L}_{\boldsymbol{\theta}}|\mathbf{L}_{\mathbf{X}}|) + (n-p)\left(1 + \log\left(2\pi \frac{d(\tilde{\mathbf{u}}, \boldsymbol{\theta}, \tilde{\boldsymbol{\beta}})}{n-p}\right)\right).$$

Coerce the w I-prior model into a mixed-model

$$\mathbf{y} = \alpha + (\lambda_{1}\mathbf{H}_{1} + \dots + \lambda_{p}\mathbf{H}_{p})\mathbf{w} + \epsilon$$

$$= \begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix} \begin{bmatrix} \alpha \end{bmatrix} + \begin{bmatrix} \mathbf{H}_{1} & \dots & \mathbf{H}_{p} \end{bmatrix} \begin{bmatrix} \lambda_{1}\mathbf{I}_{n} \\ \vdots \\ \lambda_{p}\mathbf{I}_{n} \end{bmatrix} \mathbf{w} + \epsilon$$

$$= \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\Lambda}_{\lambda}\mathbf{w} + \epsilon$$

$$= \mathbf{X}\boldsymbol{\beta} + \mathbf{Z} \underbrace{\begin{pmatrix} \frac{1}{\sigma^{2}}\boldsymbol{\Lambda}_{\lambda} \end{pmatrix}}_{\Lambda_{\theta}} \underbrace{(\sigma^{2}\mathbf{w})}_{\mathbf{u}} + \epsilon$$

$$= \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\Lambda}_{\theta}\mathbf{u} + \epsilon$$

- Our scale parameters are contained in $\theta = (\lambda_1/\sigma^2, \dots, \lambda_p/\sigma^2)$.
- Problem: Our **Z** matrix is dense, so not able to use sparse Cholesky methods.

Haziq Jamil (LSE) 3 Nov 2016 41 / 36

MLE vs Bayes for scale parameters

• For each $k=1,\ldots,p$, the maximum a posteriori (MAP) estimate is

$$\begin{split} \hat{\lambda}_k^{MAP} &= \argmax_{\lambda_k} f(\alpha, \boldsymbol{\beta}, \psi, \boldsymbol{\lambda} | \mathbf{y}) \\ &= \argmax_{\lambda_k} f(\mathbf{y}, \boldsymbol{\beta} | \alpha, \psi, \boldsymbol{\lambda}) f(\psi) f(\lambda_1) \cdots f(\lambda_p) \\ &= \argmax_{\lambda_k} f(\mathbf{y}, \boldsymbol{\beta} | \alpha, \psi, \boldsymbol{\lambda}) f(\lambda_k) \end{split}$$

whereas the ML estimate is

$$egin{align} \hat{\lambda}_k^{ML} &= rg\max_{\lambda_k} f(\mathbf{y}; oldsymbol{\lambda}, \psi) \ &= rg\max_{\lambda_k} \int f(\mathbf{y}, oldsymbol{eta}; oldsymbol{\lambda}, \psi) \, \mathrm{d}oldsymbol{eta} \end{split}$$

• $\hat{\lambda}_k^{MAP} = \hat{\lambda}_k^{ML}$ if the beta I-prior model is marginalised over β , and a uniform prior is used for each λ_k .
